

HEP NTUA Weekly Report

11/1/2021

George Bakas

Summary

Angular Distributions, Z' analysis:

- Significance plots:
 - 1TeV – 2TeV mJJ Cut every 250GeV
 - Significance vs mJJ Cut for every Zprime mass, width pair
 - Full Run II (2016, 2017, 2018)
 - Search for the maximum significance for every mJJ Cut
- $Significance = \frac{Signal}{\sqrt{Signal+Background}}$, where signal is the Zprime events and bkg \rightarrow ttbar, qcd, subdominant
- Expected limits for 2016:
 - Masses 2000, 2500, 3000 and 4000 GeV for 1% widths
 - Chi distribution asymptotic (Expected) limits vs mJJCut

Significance Plots 2016, width 1%

Significance_M2000_W20

Significance_M2500_W25

Significance_M3000_W30

Significance_M4000_W40

Expected Limit Plots 2016, width 1%

Expected Limits for Z' (M:2000, W:20)

Expected Limits for Z' (M:2500, W:25)

Expected Limits for Z' (M:3000, W:30)

Expected Limits for Z' (M:4000, W:40)

BACKUP

Summary

Angular Distributions, Z' analysis:

- New Signal Region:
 - $SR_C = SR + m_{JJ} > 1.5\text{TeV}$
- Stack histograms for SR_C
- Asymptotic Limits (Brazilian plots) for 2016, 2017, 2018
 - Total Cross section x BR
 - Total Cross section = $\sum_{i=1}^N S_i$, where S_i is the signal yield in the reconstructed level
- X distributions show a different slope than the B2G-16-015
 - Recreated Brazilian plot using m_{JJ} variable (only for 2016 and Zprime 1% width)
 - Tried to increase mass cut from 1.5 TeV to 2 TeV to improve sensitivity → not enough events coming from signal extraction
 - If I use $t\bar{t}$ MC (χ dists) as input, the shape is the same as with the 1.5 TeV cut
 - Maybe sliding mass cuts? For each Z' use a different m_{JJ} cut

Signal Selection

Variables	Selected Cut
pT (both leading jets)	> 400 GeV
Njets	> 1
N leptons	= 0
eta (both leading jets)	< 2.4
mJJ	> 1000 GeV
jetMassSoftDrop (only for fit)	(50,300) GeV
Top Tagger	> 0.2, 0, 0.1
B tagging (2 btagged jets)	> Medium WP
Signal Trigger	

Control Region Selection

Variables	Selected Cut
pT (both leading jets)	> 400 GeV
Njets	> 1
N leptons	= 0
eta (both leading jets)	< 2.4
mJJ	> 1000 GeV
jetMassSoftDrop (only for fit)	(50,300) GeV
Top Tagger	> 0.2, 0, 0.1
B tagging (0 btagged jets)	< Medium WP
Control Trigger	

Signal Extraction

$$S_{1.5TeV}(x_{reco}) = D_{1.5TeV}(x_{reco}) - QCD_{1.5TeV}(x_{reco}) - Sub_{1.5TeV}(x_{reco}) \rightarrow$$

$$\text{Where } QCD_{1.5TeV}(x_{reco}) = D_{1.5TeV,shape}^{0-btag}(x_{reco}) \times N_{SR(1.5TeV)} \times C_{closure}^{shape SF}$$

$$\text{and } N_{SR(1.5TeV)} = R_{yield}^{1TeV \rightarrow 1.5TeV} \times N_{SR(1TeV)}^{QCD} = R_{yield}^{1TeV \rightarrow 1.5TeV} \times R_{yield}^{SRA \rightarrow SR} \times N_{SRA}^{QCD}$$

- The variable of interest here: $x_{reco} \rightarrow \chi$
- 1.5 TeV refers to the mJJ cut
- We deploy a fit in the Signal Region (2btag) to extract the N_{QCD}^{fit} in SRA (mJJ > 1TeV)

$$D(m^t)^{(i)} = N_{tt}^{(i)} T^{(i)}(m^t, k_{MassScale}, k_{MassResolution}) + N_{bkg}^{(i)} B(m^t)(1 + k_1 x) + N_{sub}^{(i)} O^{(i)}(m^t)$$

Top Angular Distributions

- We employ the dijet angular variable χ from the rapidities of the two leading jets
- Why χ ?
 - The distributions associated with the final states produced via QCD interactions are relatively flat in comparison with the distributions of the BSM models or new particles, which typically peak at low values of χ
- We can measure the variable χ in two ways

1. By measuring the difference of the rapidities of the two leading jets such as the corresponding rapidity in the ZMF is:

$$y^* = \frac{1}{2}(y_1 - y_2)$$

χ is defined as $\chi = e^{|y^*|} = e^{|y_1 - y_2|}$ (1) and can be measured by creating the TLorentzVector, boost it to the ZMF and find the rapidity difference of the two leading jets

2. By measuring the scattering angle θ^* (angle between top quark and z-axis in the Zero Momentum Frame)

We define as $y^* = \frac{1}{2} \ln\left(\frac{1+|\cos\theta^*|}{1-|\cos\theta^*|}\right)$ and from (1) we can find that:

$$\chi = \frac{1 + |\cos\theta^*|}{1 - |\cos\theta^*|}$$
